(54) Title: METHOD AND APPARATUS FOR PRINTING A RIBBON FOR PACKAGING GELATIN CAPSULES

(57) Abstract

Apparatus for producing image bearing filled gelatin capsules has guide rollers (12 and 16) for directing gelatin ribbon (2, 4) from respective casting drums to an encapsulation station (6). Along the path of at least one ribbon (4) is a transfer station (18) at which images are applied to the ribbon. The images are applied in a pattern which corresponds to the pattern of capsules formed from the ribbon at the encapsulation station (6). Both the rollers (8) at the encapsulation station, and a support roller at or adjacent the transfer station are positively driven, and a control system ensures that the peripheral speed of a support roller (16) in the transfer station (18) is the same as the speed of the ribbon into and through the encapsulation station. The drive motor for the respective support roller in the transfer station is preferably a stepping motor, adjustable to advance or retard relative to the ribbon speed in the encapsulation station (6). Sensors (28, 64) may be included to positively monitor the alignment of ribbon with the encapsulation process. Provision is also made for monitoring the lateral positioning of images on the ribbon, and for shifting the ribbon to accommodate any lateral misalignment.

METHOD AND APPARATUS FOR PRINTING A RIBBON FOR PACKAGING GELATIN CAPSULES

This invention relates to the encapsulation of products within a gelatin shell derived from a ribbon thereof. The invention is concerned particularly with the printing of indicia on the gelatin ribbon such that the indicia appears in a predeterminable manner on the capsule products.

The encapsulation of a wide range of products in gelatin shells is long-established. The basic technique is described in U.S. Patent No. 2234479, and it has of course been substantially developed since then. Nevertheless, modern encapsulation machinery still draws gelatin ribbon from two sources to a charging station where sections of gelatin strip from both ribbons are sealed around the respective contents. Encapsulation is normally accomplished using a flat or a roller dye technique. A typical roller dye technique is described in an article entitled "Soft gelatin capsules: a solution to many tableting problems" published in Pharmaceutical Technology in September 1985.

Gelatin capsules are normally made using soft gelatin and in its ribbon form prior to encapsulation it is highly flexible and deformable. Gelatin may be blended with other components to vary its characteristics in different ways for different applications. However, the term "gelatin" is used herein to encompass a range of gelatin based compositions which are used in encapsulation processes. Because of its flexibility and deformability, while various methods have been proposed for applying markings to gelatin ribbon which appear on the resulting capsule, it has not been possible to accurately locate specific indicia on a gelatin ribbon such that the indicia appear in a predeterminable manner on the resultant capsules.

Pursuant to the above, the present invention is directed at apparatus for producing image bearing filled

gelatin capsules comprising an encapsulation station having formation and fill means; a guidance mechanism for feeding strips of gelatin ribbon into juxtaposition at the encapsulation station and a transfer station for applying a desired image to at least one of the strips in the path of the ribbon to the encapsulation station. The transfer station comprises support rollers on one or both sides of the path of the strip, and a motor for driving at least one of the support rollers. A control system is provided for monitoring the speed of the strip into the encapsulation station, and driving at least one support roller at a peripheral speed equal thereto. The ribbon is positively driven into and through the encapsulation station, and positive driving of the support roller or rollers is necessary if the images or indicia to be applied are to be in proper register, in order to take account of stretching or other distortion of the gelatin ribbon. Conveniently, the ribbon is driven at both locations by rollers of equal diameter, at the same rotational speed. Any suitable means may be used for applying images to the gelatin; suitable printing mechanisms including ink jet printers and roller printing direct from one of the support rollers. Suitable ink jet printers are available from Image UK Limited, of Hook, Chester CHD 3AD, England. Particularly preferred roller printing systems are flexographic systems.

The drive motor for the respective support roller in the transfer station is preferably a stepping motor, which can be adjusted to advance or retard relative to the ribbon speed at the encapsulation station. The control system can be used to directly monitor the position of images on the strip in its direction of travel as it enters the encapsulation station, or the position of the formation means in the encapsulation station, and to adjust the drive motor accordingly, to maintain a predetermined position of the images or indicia in the encapsulation station. Suitable stepping motors and

control systems are available from Simplatroll Limited of Bedford, England.

5 The control system can be used to ensure that once the print system is set up, any change in machine speed will automatically lead to adjustment such that the print roll runs at the same speed. The initial set-up is by using a small micro-processor/programme to adjust the vertical alignment in very small increments of for example 0.25 mm, to allow print to be centralised on the dies at 10 the encapsulation station. The positioning of the print roller with the dies can be indexed by picking up a signal from a fixed point on the dies and a fixed point on the print roller to continually monitor their positions.

15 The nature of gelatin, particularly in ribbon form, is such that it can easily shift laterally on guide rollers, and the invention also provides for such lateral shift to be corrected. This can be accomplished by enabling lateral movement of one or more support rollers relative to the path of the strip to correct any 20 misalignment of the applied images or indicia in the encapsulation station. Using an alternative technique, this is achieved using an applicator guide assembly including a guide roller; sensing means for monitoring lateral movement of the imaged strip on the guide roller; 25 a locator roller mounted for rotation about a pivotal axis; and means for pivoting the locator roller relative to the guide roller to shift strip laterally thereon. The strip will normally pass between the guide and locator rollers. In the lateral shifting or correction of the 30 strip, flexibility and deformability of the gelatin is of considerable assistance as it enables this lateral adjustment to be accomplished without difficulty and more importantly, without shutting down the apparatus itself.

35 In another preferred feature of the invention, where the printing device is a roller printer, the support roller is mounted for rotation on a fixed axis and the print roller is mounted for rotation about an axis movable

towards and away from the support roller axis. This enables the pressure between the rollers to be controlled and more importantly where the other roller is a printing roller, to be maintained substantially constant to ensure consistent print quality on the gelatin ribbon. A constant force can typically be provided by an air pressure mechanism. Various different mechanisms can be used to provide for adjusting the force and different pressures may be developed along the length of the rollers if for some reason this was desired. Similarly, the colour and/or nature of the ink or inks used can be varied, enabling the generation of ornamental patterns of different colours on the encapsulated product.

Another problem that arises in the application of indicia to gelatin strips or ribbon is clarity of outline. The problem arises because of the inherent flexibility and elasticity of the gelatin, and also inconsistent metering of ink onto the printing roller. In known printing techniques this problem has been addressed by the use of printing rollers with roughened or screened surfaces, but while this has been effective when the image is being applied to paper or board for example, when used to deliver ink to gelatin unsatisfactory image outlines can be the result. However, we have found that we can take advantage of the benefits derived from the use of a screened or roughened roller surface in the printing process if a roller with a screened surface is used as a transfer or inking roller carrying ink from a reservoir to the printing roller. With ink from the reservoir being retained in rather than on the screened surface, the inking roller surface can be wiped, preferably with a doctor blade, prior to its engagement with the printing roller while still bearing sufficient ink for transfer to the printing roller and subsequent application to the gelatin ribbon or strip. This technique results in consistent and predictable quantities of ink being transferred from the inking roller to the printing roller,

and assists in preserving sharp image outlines on the printing roller.

5 Rollers with screened or roughened surfaces are available in the United Kingdom under the registered Trade Mark ANILOX from Sun Chemical Limited of Watford, Hertfordshire. The surface of these rollers is chrome hardened, and rollers can be provided with different degrees of screening or roughening. The roller surface is
10 formed with an array of pockets, typically 100, 150 or 200 lines per inch (equivalent to 10,000; 22,500; or 40,000 pockets per square inch), with the largest pockets (10,000 per square inch) having the greatest depth. It will be appreciated that by wiping or scraping the roller surface, ink is retained in the pockets and is readily transferred
15 therefrom to the printing roller. The required degree of screening or roughening is normally determined relative to the ink and the colour of the ink that is being printed.

Rollers of the kind described above are particularly suited for use in flexographic printing systems of the
20 kind referred to earlier. In flexographic printing systems, ink is carried from a reservoir via a fountain roller and a transfer roller to a printing roller which is applied to the substrate upon which the image is to be printed. The transfer roller has the screened or
25 roughened surface and provides a means for accurately controlling the amount of ink carried to the printing roller. Flexographic printing systems have been used for printing onto a wide range of substrates, and could be operated at very high speeds. Roller speeds in excess of
30 100 rpm were common. In the practice of the present invention, the speed of the printing process is dramatically less than that normally used in Flexographic systems, with the gelatin ribbon strip moving typically at a speed of around 2.5 cm per second, equivalent to a
35 printing roller speed of around 3 rpm. With these relatively low speeds, there is a risk of ink drying on the rollers, and particular care has to be taken to avoid

or at least minimise this eventuality. Self-cleaning transfer and printing rollers are available and additionally, particular care can be taken in selecting appropriate inks. Suitable inks for use in the present invention are available under the names OPACODE from Colorcon Limited of Orpington, Kent, England; and MASTERCOTE from Warner Jenkinson of Kings Lynn, Norfolk, England. In addition to selecting a suitable ink, in the practice of the present invention the risk of drying ink is further reduced by removing the fountain roller from the traditional sequence in a flexographic printing system, and have the transfer roller receive ink direct from the reservoir or tray.

The invention will now be described by way of example, and with reference to the accompanying schematic drawings wherein:

Figure 1 is a representation of apparatus according to the invention;

Figure 2 is a perspective view showing a transfer station of the kind used in the apparatus of Figure 1;

Figure 3 is a perspective view of an alternative monitoring system for the gelatin ribbon;

Figure 4 illustrates apparatus according to the invention which requires the ribbon to twist in its path to the encapsulation station; and

Figure 5 is a representation of another embodiment of apparatus according to the invention.

The apparatus diagrammatically illustrated in Figure 1 shows the path of two gelatin ribbons 2, 4 from respective casting drums to an encapsulation station 6 comprising roller dyes 8 which combine with a fill mechanism (not shown) coupled to a wedge 10 to encapsulate fill material in a conventional manner. The ribbon 2 is carried to the encapsulation station 6 around rollers 12 and over a feed bar 14. The path of ribbon 4 is around rollers 16, and a sensing device 28. One of the rollers

16 is part of a transfer station 18 at which images are applied thereto from printing roller 20. Ink is applied to the printing roller 20 from transfer or inking roller 22 disposed over ink bath 24.

5 The roller dyes 8 at the encapsulation station 6 are
formed with recesses which are in juxtaposition when they
reach the nip and are filled. In order to properly locate
images applied to the ribbon 4 on formed capsules, it is
of course essential that the applied images properly
0 register with the recesses.

The inking roller 22 has a screened or roughened surface comprising an array of pockets. A roller having a particular pocket density on its screened surface will be selected depending upon the ink that is being used and the required printing effect. As a general guide, larger pockets will be used for lighter colours where a greater quantity of ink must be transferred to ensure that the requisite image is created on the ribbon surface. Because of the retention of the ink in rather than on the surface of the inking roller 22, its surface can be scraped or wiped at the pocket peripheries with the retained ink being a predictable metered quantity. This enables the density of colour in the printed image to be accurately established, and by this means, a reliable quality of printing can be achieved.

As can be seen, the gelatin ribbon 4 bearing images transferred thereto from printing roller 20 is carried around to the encapsulation station 6 where the device 28 monitors the location of images on the ribbon relative to the recesses in the roller dye 8 in which the capsules will be formed. The device 28 is located such that the ribbon section and roller dye section that it scans are equidistant from the roller nip. Thus, it can immediately establish whether a printed image is in proper registry with a respective recess and if not, what correction is required. Signals generated by the scanning device 28 are transmitted to a control device (not shown) which adjusts

the speed of the printing roller 20 as appropriate.

The transfer station 18 is illustrated in more detail in Figure 2. The print roller 20 is driven by a stepping motor 30. The shaft coupling the roller 20 to the motor 30 bears a gear wheel 32 which meshes with another wheel 34 which drives the inking roller 22. An encoder (not shown), typically mounted on one of the rollers 8 in the encapsulation station monitors the rotation of the rollers and thereby the location of the recesses in the rollers 8 in the nip. The encoder is coupled to the stepping motor 30 which is thereby synchronised with the motor driving the roller dyes 8. However, in the event that for some reason this synchronism is lost, the incorrect lengthwise alignment of images printed on the ribbon 4 with the recesses in the roller dyes 8 is sensed by the device 28, and the stepping motor is automatically adjusted appropriately to bring them back into synchronism.

The entire transfer station is mounted on a plate 36 which is itself movably mounted on a printer generally indicated 38. When the encapsulating apparatus is initially assembled, the lateral location of the printing roller 20 relative to the adjacent guide roller 16 and hence the ribbon 4 is set by adjustment of wheel 40. Wheel 40 is part of a worm gear mechanism which locates the plate 36 relative to the printer 38, which mechanism also includes a gear box 42. The gear box 42 has its own drive, also adapted to receive signals from the scanning device 28 such that once the encapsulating apparatus is in operation, lateral misalignment of images on the ribbon fall as monitored by the device 28 is compensated. In this respect it should be noted that the lateral shift of the print roller 20 relative to the guide roller 16 will eventually shift the printed images relative to the ribbon 4. The flexibility of the ribbon 4, to which reference is made above, enables such movements to be readily accommodated.

The ink roller 22 is a screened roller, and functions

in known manner to transfer ink from the tray 24 to the print roller 20. A doctor blade 44 is used to wipe the screened surface of the inking roller 22 as described above. However, if a smooth surfaced inking roller 22 is used, then a knife can be used in the traditional way to set the weight of ink transferred.

The print roller 20; inking roller 22 and ink tray 24, together with the relevant drive units 30, 32 and 34 are mounted on a common plate 48 which is itself mounted on plate 36 for lateral movement relative to the respective roller axis towards and away from the guide roller 16. A pneumatic cylinder 50 applies a continuous pressure urging the plate 48 and hence the printing roller 20 towards the guide roller 16 and thus determines the pressure at which the printing roller 20 engages the gelatin ribbon 4.

Provision is also made in the apparatus illustrated in Figure 2 for adjusting the alignment of the print roller 20 and the inking roller 22 to achieve differential inking weights across the axial length thereof. Further, provision may also be made for deliberately inclining the axis of the print roller 20 to the axis of the guide roller 16 to obtain a differential printing pressure on the ribbon along a transverse section thereof. These features can be of value when using different inks for images to be created along a transverse section of ribbon 4.

An alternative system for monitoring and controlling the registry of the printed images with the rollers 8 in the encapsulation station is shown in Figure 3. An applicator guide bar assembly 52 adjusts and sets the lateral alignment of the ribbon prior to its entry into the encapsulation station 6. It can effectively replace not only the sensing device 28, but also one of the rollers 16. The path of the ribbon (not shown in Figure 3) is upwards as indicated by arrows 54 between front guide 56 and sparge tube 58 mounted on the assembly frame.

From the sparge tube 58 the ribbon passes as indicated by arrows 60 over bracket 62 to the final guide roller 16 and thence to the encapsulation station 6. A marginal edge portion of the ribbon passes over two optic sensors 64 which can monitor the position of either the edge of the ribbon, or a marker line thereon applied by a ridge 66 on the print roller 20 at the transfer station. Any lateral movement of the edge or the marker line beyond a predetermined limit is sensed, and in response thereto the axis of the front guide is re-oriented by instruction from a computer (not shown) to guide the edge or marker line back into place. The primary mechanism for accomplishing this is a linear actuator motor 68, adapted to raise or lower one end of the front guide relative to the sparge tube. The guide bar assembly also includes adjusters 70 for initial setting of the front guide when the apparatus is first installed. The optic sensors 64 can themselves be adjusted, both translationally together across the frame, and relative to each other by a mechanism 32 for different ribbon sizes and required accuracy of lateral alignment. The assembly 52 also carries an optic sensor 74 on the frame for monitoring the longitudinal registry of the printed images with the rollers 8 in the encapsulation station 6. Signals for sensor 74 are likewise transmitted to the computer which in turn instructs the stepping motor 30 as required.

For reasons of space, the layout of the elements in a gelatin encapsulating machine would not in practice normally be that shown in Figure 1. Most significantly, the gelatin casting drums would be turned through 90° to be aligned on substantially the same axis perpendicular to the axes of the rollers 8 in the encapsulation station. This arrangement is illustrated in Figure 4 which shows the path of ribbon 4, to which images are applied, in apparatus which is fitted with an applicator guide bar assembly 52 of the kind shown in Figure 3 in place of one of the rollers 16 of Figure 1. Figure 4 also shows the

train of smoothing and stretching rollers in the path of ribbon from the casting drum to the transfer station 18. As can be seen, the arrangement shown requires the ribbon to twist between the transfer station 18 and the applicator guide bar assembly, which itself increases the importance of monitoring any movement of the imaged ribbon out of registry with the rollers in the encapsulation station, particularly lateral movement.

The path of ribbon 2 from its casting drum to the encapsulation station 6 is essentially a mirror image of that shown in Figure 4, but omitting the transfer station 18. An applicator guide bar assembly can be included, particularly to monitor lateral movements of the ribbon 2. For the unmarked ribbon of course, the sensors 64 will monitor the position of the ribbon edge only. Longitudinal registry of the ribbon 2 with the encapsulation station does not normally required monitoring.

The above discussion of the invention describes the apparatus using transfer printing systems. However, the invention is not limited to such systems. Other printing mechanisms may be employed. They could be located between guide rollers in the path of the gelatin strip on its route to the encapsulation station. Thus, in the apparatus described above, the transfer station is effectively replaced by the guide rollers. A preferred alternative printing system is one including an ink jet printer. Ink jet printers can produce clear images on gelatin strips. Figure 5 illustrates apparatus according to the invention embodying this alternative, and also shows an arrangement in which printing can be applied to both gelatin ribbons, each monitored by an applicator guide bar assembly 52. Ink jet printers 76 are fitted between pairs of rollers 12 and 16 respectively. The other reference numerals in Figure 5 correspond with those used in the other drawings.

CLAIMS:

1. Apparatus for producing image bearing filled gelatin capsules from gelatin ribbon, having an encapsulation station with formation and fill means; a guidance mechanism for feeding strips of gelatin ribbon into juxtaposition at the encapsulation station; a transfer station for applying images to at least one of the gelatin ribbon strips in their path to the encapsulation station, which transfer station comprises a printing device for applying images to said one strip, a support roller for said one strip, and a motor for driving the support roller; and a control system for monitoring the speed of the strip in the encapsulation station and driving the support roller at a peripheral speed equal thereto.
2. Apparatus according to Claim 1 wherein the printing device is an ink jet printer.
3. Apparatus according to Claim 1 wherein the printing device comprises a printing roller and means for urging it against the support roller to form a nip therebetween for the passage of the gelatin strip.
4. Apparatus according to Claim 3 wherein the support roller is mounted for rotation on a fixed axis and the printing roller mounted for rotation about an axis movable toward and away from the roller axis, the printing roller being urged against the support roller by a constant force.
5. Apparatus according to Claim 4 wherein said constant force is provided by air pressure.
6. Apparatus according to Claim 4 or Claim 5 wherein the constant force is adjustable.

7. Apparatus according to any preceding Claim wherein the printing device includes multiple ink sources for applying ink of different colours to the gelatin strip.
- 5 8. Apparatus according to any preceding Claim wherein the drive motor is a stepping motor, adjustable to advance or retard relative to the strip speed.
- 10 9. Apparatus according to Claim 8 wherein the control system includes means for monitoring the position of images on the strip in its direction of travel, and for adjusting the drive motor to maintain a predetermined position in the encapsulation station.
- 15 10. Apparatus according to Claim 8 wherein the control system includes means for monitoring the position of the formation means at the encapsulation station, and for adjusting the drive motor to maintain synchronism between the movement of the strip through the formation means and transfer station.
- 20 11. Apparatus according to any preceding Claim including means for controlling the lateral alignment of the imaged strip.
- 25 12. Apparatus according to Claim 11 wherein said one support roller in the transfer station is mounted for axial adjustment, transverse to the path of the strip, for alignment of the applied images in the encapsulation station.
- 30 13. Apparatus according to Claim 11 wherein the controlling means comprises an applicator guide assembly including a guide roller; sensing means for monitoring lateral movement of the imaged strip on the guide roller; a locator roller mounted for rotation about a pivotal axis; and means for pivoting the locator
- 35

roller relative to the guide roller to shift strip laterally thereon.

5 14. Apparatus according to Claim 13 wherein the guide bar assembly allows passage of the strip between the guide roller and the locator roller.

10 15. Apparatus according to Claim 13 or Claim 14 wherein the locator roller tapers from a central cross-section to each axial end thereof.

15 16. Apparatus according to any of Claims 13 to 15 wherein the sensing means monitors the lateral position of an edge of the strip.

17. Apparatus according to any of Claims 13 to 15 wherein the sensing means monitors a line extending longitudinally on the strip.

20 18. Apparatus according to Claim 17 wherein the transfer station includes means for applying said line to the strip.

25 19. A method of producing image bearing filled gelatin capsules comprising feeding gelatin strips into juxtaposition at an encapsulation station having formation and fill means; applying images to at least one of the strips in a transfer station on its path to the encapsulation stations; monitoring the translational speed of the one strip in the encapsulation station; and
30 driving the strip through the transfer station at a speed equal to that of its passage through the encapsulation station.

35 20. A method according to Claim 19 including the step of adjusting the speed of the strip in the transfer station to correct an error in the longitudinal position

of the images on the strip in the encapsulation station.

21. A method according to Claim 19 or Claim 20 including the step of monitoring the lateral alignment of images on the strip in the encapsulation station, and shifting the strip transversely to correct any misalignment.

22. A method according to Claim 21 wherein the lateral alignment of the strip is monitored by observing an edge of the strip or a line applied to the strip adjacent said edge, and monitoring its movement outside a range of permissible shift.

23. A method according to Claim 22 wherein the line is applied at the transfer station.

24. Apparatus for producing image bearing filled gelatin capsules from gelatin ribbon, comprising an encapsulation station having formation and fill means; a guidance mechanism for feeding strips of gelatin ribbon into juxtaposition at the encapsulation station; a transfer station for applying a said image to at least one of the strips in the path of the ribbon to the encapsulation station, which transfer station has printing and support rollers on either side of the path of the strip; an inking roller in rolling engagement with the printing roller and for drawing ink thereonto from a reservoir, which inking roller has a screened surface; and means for wiping the inking roller surface prior to its engagement with the printing roller.

25. Apparatus according to any of Claim 3 or any Claim appendant thereto wherein the transfer station includes an inking roller in rolling engagement with the printing roller and for drawing ink thereonto from a reservoir, which inking roller has a screened surface; and means

for wiping the inking roller surface prior to its engagement with the printing roller.

5 26. Apparatus according to Claim 24 or Claim 25 wherein the screened surface of the inking roller comprises a tight array of pockets.

10 27. Apparatus according to Claim 14 wherein the array comprises at least 100 lines per inch (40/cm), each having a minimum depth of 25 μ m.

15 28. Apparatus according to Claim 14 wherein the array comprises substantially 100 lines per inch (40/cm), each having a depth of substantially 50 μ m.
